Introduction: *In situ* exploration of Saturn's at-
mosphere would bring insights in two broad themes:
the formation history of our Solar System and the pro-
cesses at play in planetary atmospheres. Here we
summarize the science case for *in situ* measurements at
Saturn (see also [1] for details) and discuss the possible
mission concepts that would be consistent with the
constraints of ESA M-class missions.

Solar System formation: To understand the for-
mation of giant planets and the origin of our Solar Sys-
tem, statistical data obtained from the observation of
exoplanetary systems must be supplemented by direct
measurements of the composition of the planets in our
Solar System. A giant planet's bulk composition de-
pends on the timing and location of planet formation,
subsequent migration and the delivery mechanisms for
the heavier elements. By measuring a giant planet's
chemical inventory, and contrasting these with meas-
urements of (i) other giant planets, (ii) primitive ma-
terials found in small bodies, and (iii) the composition of
our parent star and the local interstellar medium, much
can be revealed about the conditions at work during the
formation of our planetary system.

Planetary Atmospheric Processes: Saturn's com-
plex and cloud-dominated weather-layer is our princi-
ple gateway to the processes at work within the deep
interior of this giant planet. *In situ* studies provide ac-
cess to atmospheric regions that are beyond the reach
of remote sensing, enabling us to study the dynamical,
chemical and aerosol-forming processes at work from
the thermosphere to the troposphere below the cloud
decks.

Mission concepts : Different mission architectures
are envisaged, all based on an entry probe that would
descend through Saturn's stratosphere and troposphere
under parachute down to a minimum of 10 bars [1].

Future studies will focus on the trade-offs between
science return and the added design complexity of a
probe that could operate at pressures greater than 10
bars. Three possible mission configurations are cur-
rently under study (with different risk/cost trades):

- **Configuration 1:** Probe + Carrier. After probe de-
livery, the carrier would follow its path and be de-
stroyed during atmospheric entry, but could perform
pre-entry science. The carrier would not be used as a
radio relay, but the probe would transmit its data to the
ground system via a direct-to-Earth (DTE) RF link;

- **Configuration 2:** Probe + Carrier/Relay. The
probe would detach from the carrier several months
prior to probe entry. The carrier trajectory would be
designed to enable probe data relay during over-flight
as well as performing approach and flyby science;

- **Configuration 3:** Probe + Orbiter (similar to the
Galileo Orbiter/Probe). As for Configuration 2, but
after probe relay during over-flight, the orbiter would
transition to a Saturn orbit and continue to perform
orbital science.

In all three configurations, the carrier/orbiter would
be equipped with a combination of solar panels, sec-
ondary batteries and possibly a set of primary batteries
for phases that require a high power demand, for ex-
ample during the probe entry phase.

Payload: To match the measurement requirements,
a model payload could include a mass spectrometer, a
tunable laser system, a helium abundance detector, an
atmospheric structure instrument, accelerometers, tem-
perature sensors, pressure profile, Doppler wind and
nephelometer instruments, etc.

Such a mission would greatly benefit from strong
international collaborations.
